ZentraOS

Connect a ClickHouse source. Get a governed semantic layer, automatically — then ask it anything, and get an answer you can actually trust.

- Team SubZentra

THE PROBLEM

Every new feature needs instrumentation, schema design, and analysis — and today that loop is manual and slow.

Teams either hand-write a semantic layer that drifts from reality the moment a table changes, or they hand an LLM raw SQL access and hope it doesn't hallucinate a metric that was never there. Neither scales, and neither is something a business can trust its numbers to.

Hand-written schemas

Someone maintains a config file mapping tables to metrics. It's stale the day a column changes, and it doesn't exist yet for a source you just connected.

Raw SQL agents

Fast to demo, impossible to trust. A model with unrestricted SQL access can invent a column, misjoin a table, or answer confidently from nothing.

THE SOLUTION

A governed semantic layer that compiles itself, and a multi-agent pipeline that never guesses.

- ▶ Connect any ClickHouse Cloud source — schema, columns, cardinality, and null rates are harvested automatically.
- ▶ Every harvested table becomes a live, queryable cube with typed measures and dimensions. No config file, no migration.
- ▶ A multi-agent pipeline plans the question, queries the governed catalog, independently re-derives the answer, and only then drafts a finding.
- ▶ Anything the pipeline isn't confident in stops at a human approval gate — it never ships a guess.

HOW IT WORKS

Orchestrator → Cube Analyst → Evaluator → Insight

|| Confidence below threshold, or a recheck that never converges → **Human Approval gate**. The pipeline stops rather than publishing a number nobody signed off on.

Every step is persisted as its own Agent Execution — role, model, provider, tokens, cost, latency, confidence, and the exact query that ran. Any published finding traces back to what actually happened.

WHY THIS WINS

Built for production trust, not a demo script.

Discovered, not declared

The catalog compiles from what's actually in ClickHouse, per tenant, at query time. Connect a different source and the agent reasons over a completely different catalog — zero code change.

A real independence check

The Evaluator never sees the Analyst's query — only its reported figures — and has to rebuild the answer from scratch. Disagreement fails the finding rather than being smoothed over.

Multi-tenant by construction

Postgres row-level security enforces tenant isolation on every governed table. Data Connection and model routing are resolved per request, never hardcoded.

Tuned for real economics

Claude Sonnet 5 on planning and analysis; a fast, cheap model on lighter classification/recheck/prose steps. Free-tier tenants get a fully-free fallback chain.

THE STACK

Built on ClickHouse, end to end.

ClickHouse Cloud

Cube (semantic layer)

Postgres + RLS

hand-written schema files — the catalog compiles
itself

THANK YOU

Connect a source.
Ask a question.
Trust the answer.
